

Gaisser–Hillas function

From Wikipedia, the free encyclopedia

The **Gaisser–Hillas function** is used in [astroparticle physics](#). It [parameterizes](#) the longitudinal [particle density](#) in a [cosmic ray air shower](#). The function was proposed in 1977 by [Thomas K. Gaisser](#) and [Anthony Michael Hillas](#).^[1]

The number of particles $N(X)$ as a function of traversed atmospheric depth X is expressed as

$$N(X) = N_{\max} \left(\frac{X - X_0}{X_{\max} - X_0} \right)^{\frac{X_{\max} - X_0}{\lambda}} \exp\left(\frac{X_{\max} - X}{\lambda}\right),$$

where N_{\max} is maximum number of particles observed at depth X_{\max} , and X_0 and λ are primary mass and energy dependent parameters.

Using substitutions

$$n = \frac{N}{N_{\max}}, \quad x = \frac{X - X_0}{\lambda} \quad \text{and} \quad m = \frac{X_{\max} - X_0}{\lambda}$$

the function can be written in an alternative one-parametric (m) form^[2] as

$$n(x) = \left(\frac{x}{m}\right)^m \exp(m - x) = \frac{x^m e^{-x}}{m^m e^{-m}} = \exp(m (\ln x - \ln m) - (x - m)).$$
